System Overview:

This software application is designed to inform users about the latest food recalls. We realized that there was little awareness surrounding food recalls and with today's wide variety of selections in grocery stores, there's so many products that have a real risk of going bad. *Consume Safe* is designed to inform the user with real-time alerts of recalls provided by the U.S. Food and Drug Administration (FDA). Furthermore, this application is meant for **everyone**, but it could be most helpful for communities who live outside the city or areas where there's generally less awareness of common food contaminations.

Access Instructions:

This is a general set of instructions that'll guide you on how to initialize the project. I recommend cloning the project first, here's a link to the GitHub Repository:

```
git clone https://github.com/rmcclain1/Capstone_Project.git
cd Capstone_Project
```

Clone the project onto your desired code editor as we'll need to traverse to several directories. We used Visual Studio Code as our editor. After cloning, navigate to the location that you downloaded Capstone_project-main.

- INSERT COMMAND HERE

To set this project up, we first start by completing several prerequisites. On your machine, using the terminal in the process, install the following:

- Node
- React Native CLI
- Ruby
- Expo CLI

If you're on mac, it's helpful to use 'brew' for installing most of these dependencies. From the list above, let's work our way down, for installing 'Node' use the following:

- brew install node

For installing the React Native Command Line Interface (CLI), use the following:

- npm install -g react-native-cli

It's worth mentioning that 'npm' should come installed with 'Node'. We can now begin by installing Ruby, using the following command:

- brew install ruby

Then follow-up by installing Rails, using the following commands:

- gem install bundler
- bundler install

Similar case as with NPM—GEM should come installed with Ruby. Finally, we need to install Expo. For this, use the following command:

- npm install -g expo-cli

Another item that has to be installed is Postgresql. The link to the download would be found here, <https://www.postgresql.org/download/>. Within the options while installing and setting up ensure that pgadmin4 is installed along with postgres, as pgadmin4 is a database manager that can help you access database information easier than running command prompt commands and allows you to query database information while the app is running. Another thing to note while installing postgres is the password field that you are required to set. If you set the password to 'admin' and leave all other information default, the project will automatically connect to the server if it is running. If you set up a different password, you will have to navigate to RecallBackend/config/database.yml and modify the password on line 27.

After having installed all the required tech, we can then launch the project. You will need 2 terminals to launch the project. Starting from the base directory of Capstone_project-main, in one terminal run

- cd RecallBackend
- bundler install
- rails db:migrate

After this, the backend will be ready to run. When ready to run, in the same terminal run the command

- rails s

This will start the server. Start up, the server will automatically populate the database with recall information from the FDA, this will take a couple of minutes.

To prepare the front end you will have to open a new terminal while leaving the server terminal running. In the new terminal, Navigate from Capstone_project-main with the command,

- cd mobile

Then run the command,

- npm install

After this the front end should be prepared to launch. To launch the front end, run the command,

- npx expo start --tunnel

Follow Expo's on-screen instructions to launch the app on:

- iOS Simulator
- Android Emulator
- or Expo Go app

This will now allow you to access the project. Follow directions after the front-end startup to launch the project on a simulator.

A public live deployment is **not available**, but testers can run the app locally using Expo, as described above.

Once you have the app running and open, navigate to the sign-up page and create an account and log-in.

Required Test Scenarios:

what do you guys think about these test cases:

Test Scenario 1 - Create an Account & Log In

- Launch the app.
- Navigate to Sign Up.
- Create a new account OR use the demo account.
- Log in and verify you reach the Home screen.

Expected Result: User successfully authenticates and sees recent FDA recalls.

Test Scenario 2 - Add a Pantry Item

- Navigate to the Pantry tab.
- Add a new item (e.g., "Milk").
- Verify the item appears in your pantry list.

Expected Result: Item appears immediately and persists after app reload.

Test Scenario 3 - View Recall Details

- On the home screen, select any recall.
- Open the Recall Details page.
- Review contamination info, product distribution, and recall reasons.

Expected Result: All fields load correctly from the backend's FDA data import.
